Unit â€“ 5 : Session â€“ 7 : SLO â€“ 1 | Event-Driven Programming â€” Definition and Applications

I. Questions & Answers

1. Event-driven programming â€” a paradigm where the flow of the program is determined by events (user actions, messages, sensor signals): the program waits in a loop and executes handler code when an event occurs, rather than following a fixed sequence.

2. Real-world example â€” a GUI application such as a calculator: nothing happens until the user clicks a button, and each click triggers the corresponding handler. (Other examples: web servers reacting to requests, JavaScript in browsers.)

3. Difference from sequential programming â€” in sequential programming statements run in a predetermined order from start to finish; in event-driven programming the order is determined at runtime by which events occur and when, with an event loop dispatching them to handlers.
